Index	17

The `I2CDevice` and `SPIDevice` helper classes make managing transaction state on a bus easy. For example, they manage locking the bus to prevent other concurrent access. For SPI devices, it manages the chip select and protocol changes such as mode. For I2C, it manages the device address.

On supported GNU/Linux systems like the Raspberry Pi, you can install the driver locally [from PyPI](#). To install for current user:

```
pip3 install adafruit-circuitpython-busdevice
```

To install system-wide (this may be required in some cases):

```
sudo pip3 install adafruit-circuitpython-busdevice
```

To install in a virtual environment in your current project:

```
mkdir project-name && cd project-name
python3 -m venv .env
source .env/bin/activate
pip3 install adafruit-circuitpython-busdevice
```

CHAPTER 1

Usage Example

See `examples/read_register_i2c.py` and `examples/read_register_spi.py` for examples of the module's usage.

CHAPTER 2

Contributing

Contributions are welcome! Please read our [Code of Conduct](#) before contributing to help this project stay welcoming.

CHAPTER 3

Documentation

For information on building library documentation, please check out [this guide](#).

4.1 Simple test

Ensure your device works with this simple test.

```

4.2 adafruit_bus_device.i2c_device - I2C Bus Device

class `adafruit_bus_device.i2c_device.I2CDevice` (*i2c*, *device_address*, *probe=True*)
 Represents a single I2C device and manages locking the bus and the device address.

Parameters

- **i2c** (*I2C*) – The I2C bus the device is on
- **device_address** (*int*) – The 7 bit device address
- **probe** (*bool*) – Probe for the device upon object creation, default is true

Note: This class is **NOT** built into CircuitPython. See [here for install instructions](#).

Example:

```

import busio
from board import *
from adafruit_bus_device.i2c_device import I2CDevice

with busio.I2C(SCL, SDA) as i2c:
    device = I2CDevice(i2c, 0x70)
    bytes_read = bytearray(4)
    with device:
        device.readinto(bytes_read)
    # A second transaction
    with device:
        device.write(bytes_read)

```

readinto (*buf*, *, *start=0*, *end=None*)

Read into *buf* from the device. The number of bytes read will be the length of *buf*.

If *start* or *end* is provided, then the buffer will be sliced as if `buf[start:end]`. This will not cause an allocation like `buf[start:end]` will so it saves memory.

Parameters

- **buffer** (*bytearray*) – buffer to write into
- **start** (*int*) – Index to start writing at
- **end** (*int*) – Index to write up to but not include; if None, use `len(buf)`

write (*buf*, *, *start=0*, *end=None*)

Write the bytes from `buffer` to the device, then transmit a stop bit.

If `start` or `end` is provided, then the buffer will be sliced as if `buffer[start:end]`. This will not cause an allocation like `buffer[start:end]` will so it saves memory.

Parameters

- **buffer** (*bytearray*) – buffer containing the bytes to write
- **start** (*int*) – Index to start writing from
- **end** (*int*) – Index to read up to but not include; if None, use `len(buf)`

write_then_readinto (*out_buffer*, *in_buffer*, *, *out_start=0*, *out_end=None*, *in_start=0*, *in_end=None*)

Write the bytes from `out_buffer` to the device, then immediately reads into `in_buffer` from the device. The number of bytes read will be the length of `in_buffer`.

If `out_start` or `out_end` is provided, then the output buffer will be sliced as if `out_buffer[out_start:out_end]`. This will not cause an allocation like `buffer[out_start:out_end]` will so it saves memory.

If `in_start` or `in_end` is provided, then the input buffer will be sliced as if `in_buffer[in_start:in_end]`. This will not cause an allocation like `in_buffer[in_start:in_end]` will so it saves memory.

Parameters

- **out_buffer** (*bytearray*) – buffer containing the bytes to write
- **in_buffer** (*bytearray*) – buffer containing the bytes to read into
- **out_start** (*int*) – Index to start writing from
- **out_end** (*int*) – Index to read up to but not include; if None, use `len(out_buffer)`
- **in_start** (*int*) – Index to start writing at
- **in_end** (*int*) – Index to write up to but not include; if None, use `len(in_buffer)`

4.3 adafruit_bus_device.spi_device - SPI Bus Device

```
class adafruit_bus_device.spi_device.SPIDevice(spi, chip_select=None, *, baudrate=100000, polarity=0, phase=0, extra_clocks=0)
```

Represents a single SPI device and manages locking the bus and the device address.

Parameters

- **spi** (*SPI*) – The SPI bus the device is on
- **chip_select** (*DigitalInOut*) – The chip select pin object that implements the DigitalInOut API.

- **extra_clocks** (*int*) – The minimum number of clock cycles to cycle the bus after CS is high. (Used for SD cards.)

Note: This class is **NOT** built into CircuitPython. See [here for install instructions](#).

Example:

```
import busio
import digitalio
from board import *
from adafruit_bus_device.spi_device import SPIDevice

with busio.SPI(SCK, MOSI, MISO) as spi_bus:
    cs = digitalio.DigitalInOut(D10)
    device = SPIDevice(spi_bus, cs)
    bytes_read = bytearray(4)
    # The object assigned to spi in the with statements below
    # is the original spi_bus object. We are using the busio.SPI
    # operations busio.SPI.readinto() and busio.SPI.write().
    with device as spi:
        spi.readinto(bytes_read)
    # A second transaction
    with device as spi:
        spi.write(bytes_read)
```
